

# Strongly dissipative surface diffeomorphisms

Sylvain Crovisier, Enrique Pujals

## Abstract

We introduce a class of volume-contracting surface diffeomorphisms whose dynamics is intermediate between one-dimensional dynamics and general surface dynamics. For that type of systems one can associate to the dynamics a reduced one-dimensional model and it is proved a type of  $C^\infty$ -closing lemma on the support of every ergodic measure. We also show that this class contains Hénon maps with Jacobian close enough to 0.

## 1 Strong dissipation

We would like to highlight two main topics in dynamical systems: the  $C^\infty$  closing lemma and the search of reduced dynamical models that encapsulates the main properties of an open class of systems.

The first one was posed by Poincaré and refers to the problem of finding periodic orbits nearby recurrent points either for a system or a  $C^r$ -perturbation. It was solved in [Pu] for the  $C^1$  category. In higher topology it remains widely open except for certain particular classes of maps: rational maps of the Riemann sphere [F, J], one-dimensional real endomorphisms [Y], and recently Hamiltonian surface diffeomorphisms [AI]. For general surfaces diffeomorphisms, it remains completely open.

The second topic is present in the whole theory of dynamics and consists in looking for simplified models that could extract the main features of systems. That approach goes from finding discrete topological representations using symbolic dynamics, first return maps for continuous dynamical systems and reducing the dimension of the space.

Related to that problem, Poincaré realized that flows may be reduced to discrete systems using one-codimensional sections. For instance, the Hénon type map  $(x, y) \mapsto (1 - ax^2 + y, bx)$  appears naturally as the first return map of some three-dimensional flows. In case when the flow is dissipative, the corresponding invertible system is area contracting, which heuristically means that the essential dynamics is confined to a one-dimensional subspace; so the initial dynamic may share some essential features of the dynamics of the interval map  $f(x) = 1 - ax^2$ . In practice, the two-dimensional systems are much more difficult to describe: much less is known for the Hénon map than for the quadratic family. Moreover, many features that are not detected by the one-dimensional reduction have no one-dimensional counterpart: for instance there exists a residual set of Hénon maps exhibiting infinitely many periodic attractors with unbounded period (Newhouse phenomenon), but generic smooth one-dimensional maps have an upper bound on the period of the attracting periodic points.

Here, we introduce a new class of dissipative surface diffeomorphisms that we call *strong dissipative diffeomorphisms* that captures certain properties of one dimensional map but keeps two-dimensional features showing all the well known complexity of dissipative surface

diffeomorphisms. The dynamics of the new class, in some sense, is intermediate between one-dimensional dynamics and general surface diffeomorphism. Moreover, under some hypothesis on the relation of the Jacobian with the  $C^1$ -norm and the oscillation of the Jacobian in the attractor, it is proved that the strong dissipativeness is an open property (see theorem 1) and it is satisfied by diffeomorphisms close to one dimensional endomorphisms, proving in particular, that the new class is also non empty (see theorem 2). The class of strongly dissipative surface diffeomorphism may be compared to the class of moderately dissipative complex Hénon maps considered in [LP]: using different tools, an upper bound on the Jacobian is used in order to control stable manifolds.

The theory of real one-dimensional dynamic is leveraged on the order structure of the interval, a feature that does not exist for the plane. However, under dissipativeness, almost every point of any ergodic measure has a stable manifold that could help “to order the trajectories”; in fact, the strong dissipative hypothesis, which is nothing else than assuming that the stable manifolds separate an attracting domain (see definition 1.1), helps to recover in the particular case of the disk a partial order and to induce a rich one-dimensional structure. Using that simple observation, the dynamic can be reduced to a continuous non-invertible map acting on an ordered one-dimensional path connected metric space (see theorem 3). One can hope that this result could lead to obtain many others that hold for one-dimensional systems. Note that for general surface homeomorphism, another reduction has been developed by Le Calvez [L]: it provides a foliation transverse to the dynamics on the complement to maximal sets of fixed points; in this case the foliation is in general not invariant and the leaves are not proper.

A clear result that highlights the richness of the strong dissipative class, is our last theorem (see theorem 4) that shows that the periodic points are dense in the support of any invariant measure (in particular, for the Hénon type maps, see corollary 1.2); in that sense, we get a  $C^\infty$  closing lemma (without perturbing) for invariant measures. This was proved in [K] for hyperbolic measures, however that result does not apply to measures that has a zero Lyapunov exponent, which is the case for instance, of surfaces diffeomorphisms with zero entropy and in particular the ones in the boundary of chaos (see [LM]). An strong application of that result is obtained in [CPT] where it is studied the structure of periodic point for strong dissipative diffeomorphisms of the disk. In short, in the last theorem, we conclude that for strongly dissipative diffeomorphisms of the disk, the closure of all periodic points contains the closure of the union of the supports of all invariant probability measures<sup>1</sup>. To conclude a general closing lemma, it would be needed to prove that generically the recurrent set is contained in that set.

Let us consider a boundaryless surface  $S$  and a  $C^r$ -diffeomorphism  $f: S \rightarrow f(S) \subset S$ , where  $r > 1$ . If  $f$  is *dissipative*, i.e. if  $|\det(Df(x))| < 1$  for any  $x \in S$ , then any  $f$ -invariant ergodic probability measure  $\mu$  which is not supported on a hyperbolic sink has one negative Lyapunov exponent and another one which is non-negative. In particular for  $\mu$ -almost every point  $x$ , there exists a well-defined one-dimensional stable manifold  $W^s(x)$ .

We introduce a class of surface diffeomorphisms which strengthen the notion of dissipation:

**Definition 1.1.** A  $C^r$ -diffeomorphism  $f: S \rightarrow f(S) \subset S$  is strongly dissipative if

---

<sup>1</sup>The case of more general domains different than the disk is addressed in [CKKP] where is studied the structure of transitive attracting sets.

- $f(S)$  is contained in a compact subset of  $S$ ,
- $f$  is dissipative,
- for any ergodic measure  $\mu$  which is not supported on a hyperbolic sink, and for  $\mu$ -almost every point  $x$ , the connected components of  $W^s(x) \setminus \{x\}$  are not contained in  $f(S)$ .

We denote  $\text{Diff}_{\text{SDiss}}^r(S)$ ,  $r > 1$ , the set of strongly dissipative  $C^r$ -diffeomorphisms.

When the Jacobian is almost constant, then the strong dissipation is an  $C^1$ -open property:

**Theorem 1.** *For any  $K > 0$  and any  $b \in (0, K^{-60})$ , consider  $f \in \text{Diff}_{\text{SDiss}}^2(S)$  satisfying*

$$\|Df(x)\| < K \text{ and } b^{16/15} < |\det f(x)| < b \text{ at any point } x \in S. \quad (1)$$

*Then, any diffeomorphism  $g$  that is  $C^2$ -close to  $f$  is strongly dissipative.*

This result is based on a kind of continuity of Pesin's blocks and uniformity of stable manifolds, which will be stated and proved in section 2. It uses that for non periodic ergodic measures, the negative Lyapunov exponent is close to (the logarithm of) the minimum contraction of  $f$ . This property is reminiscent of the works on the non-uniform hyperbolicity of some Hénon maps [BC].

We will show that the strong dissipation is satisfied by dynamics close to one-dimensional endomorphisms. That result is stated in its full generality in subsection 4 but to motivate it, let us present now how it applies to the Hénon map:

**Theorem 2** (Version for the Hénon map). *For any  $a \in (1, 2)$  and for  $|b| > 0$  small, the Hénon map*

$$H_{a,b}: (x, y) \mapsto (1 - ax^2 + y, -bx) \quad (2)$$

*is strongly dissipative on the surface  $S = \{(x, y) : |x| < 1/2 + 1/a, |y| < 1/2 - a/4\}$ .*

The following shows that, conversely to the previous theorem, strongly dissipative diffeomorphisms (in particular Hénon maps with  $|b|$  small) have a one-dimensional structure. This somewhat generalizes Williams construction [W] of branched manifolds associated to hyperbolic surface attractors: in that case, the reduction obtained through the quotient of the stable manifolds gives an endomorphism on a branched one-dimensional manifold. For strongly dissipative theorem, even lacking a uniformly stable foliation, using the strong dissipation, a reduced one-dimensional dynamics is obtained as a continuous non-invertible map acting on a real tree.

We recall that a real tree is a path connected metric space such that for any two points  $a, b$  there exists a unique subset homeomorphic to  $[0, 1]$  whose endpoints are  $a$  and  $b$ .

**Theorem 3.** *Let  $f \in \text{Diff}_{\text{SDiss}}^r(\mathbb{D})$ ,  $r > 1$ , be a strongly dissipative diffeomorphism of the disc  $\mathbb{D}$ . Then there exists a semi-conjugacy  $\pi: (\mathbb{D}, f) \rightarrow (X, h)$  to a continuous map  $h$  on a compact real tree which induces an injective map on the set of non-atomic ergodic measures of  $f$ .*

As an application of the notion of strong dissipation, we show that the periodic points approximate the support of any invariant measure, generalizing the result for one-dimensional endomorphisms. Our argument also provides a simpler proof of the result presented in [Y] (see the section 6) and also proving that periodic points are dense in the non-wandering set of a compact real tree as defined above.

**Theorem 4.** *For  $f \in \text{Diff}_{\text{SDiss}}^r(\mathbb{D})$ ,  $r > 1$ , the support of any  $f$ -invariant probability  $\mu$  is contained in the closure of the periodic points. In particular if  $f$  preserves a non-atomic ergodic measure, then there are infinitely many periodic points with unbounded period.*

As a consequence we obtain:

**Corollary 1.2.** *For any  $a \in (1, 2)$  and for  $|b| > 0$  small, the support of any probability measure  $\mu$  which is invariant by the Hénon map  $H_{a,b}$  is contained in the closure of the periodic points.*

**Acknowledgements.** This work started during the preparation of [CKKP] and we are indebted to Alejandro Kocsard and Andres Koropecki for the discussions we exchanged on this topic.

## 2 Stable manifolds

The proof of theorems 1 and 2 requires a strong version of the stable manifold theorem for non-uniformly hyperbolic orbits.

**Theorem 5** (Stable manifold at non-uniformly hyperbolic points). *Consider a compact set  $\Lambda \subset S$ , two neighborhoods  $U, V$  and a  $C^2$  local diffeomorphism  $f: U \rightarrow V$ . We also assume that there exists  $\sigma \in (0, 1)$  such that*

$$\|Df^{-1}\|^{-1} < \sigma < \min(\|Df^{-1}\|^{-1/2}, \|Df^{-1}\|^{-1} \|\det Df\|^{-1/3}). \quad (3)$$

*Then, the points  $x \in \cap_{n \geq 0} f^{-n}(\Lambda)$  having a direction  $E \subset T_x S$  satisfying for each  $n \geq 0$*

$$\|Df^n(x)|_E\| \leq \sigma^n, \quad \text{and} \quad \|Df^n(x)|_E\|^2 \leq \sigma^n |\det Df^n(x)|, \quad (4)$$

*have a one-dimensional stable manifold varying continuously for the  $C^1$ -topology with  $x, f$ .*

**Remarks 2.1.** 1. The conditions on  $\sigma$  are not optimal. Note that such a  $\sigma$  exists if for instance  $f$  has constant Jacobian equal to  $b$  satisfying  $b\|Df\|^3 < 1$ .

2. The second part of condition (4) can be restated (see also [PR]):  $E$  repels exponentially for the action on the directions. More precisely,  $Df$  induces an action on the unit tangent bundle; if  $\gamma_x(E)$  denotes its derivative at  $(x, E)$  along the circle  $T_x^1 S$ , then  $|\gamma_x^n(E)| \geq \sigma^{-n}$  for each  $n \geq 0$ .
3. This result implies the stable manifold theorem of Pesin theory for some surface diffeomorphisms but gives also in some cases a uniformity with respect to the measure.
4. This result is close to [BC, section 5] where stable manifolds are obtained by successive approximations.

*Proof.* Let us consider  $x$  and  $E$  as above and let us choose  $\lambda \in (\sigma, 1)$ . By the assumptions (3) on  $\sigma$ , one can also require

$$\lambda < \min(\|Df^{-1}\|^{-1/2}, \|Df^{-1}\|^{-1} \|\det Df\|^{-1/3}). \quad (5)$$

For later use, one also chooses  $C_0 > 0$  such that

$$C_0 > \sum_{k \geq 0} (\sigma/\lambda)^k \text{ and } C_0 > \frac{1}{1 - \lambda^2 \|Df^{-1}\|}. \quad (6)$$

The dynamics of  $f$  in a neighborhood of the forward orbit of  $x$  can be lifted by the exponential map to the tangent bundle as maps  $g_n: T_{f^n(x)}S \rightarrow T_{f^{n+1}(x)}S$  defined on uniform neighborhoods of 0. Let  $F := E^\perp$ . One considers the orthogonal decomposition  $T_{f^n(x)}S = E_n \oplus F_n$  such that  $E_n := Df^n(E)$  and  $F_n = E_n^\perp$ . We then set

$$m_n = \|Df|_{E^n}(x)\| \text{ and } M_n = |\det(Df^n(x))|/m_n.$$

In these coordinates, the map  $Dg_n(0)$  has the form  $\begin{pmatrix} m_{n+1}/m_n & * \\ 0 & M_{n+1}/M_n \end{pmatrix}$ .

Note that

$$\|Df^{-1}\|^{-1} \leq \frac{m_{k+1}}{m_k} \leq \|Df\|, \quad M_{k+1}/M_k \leq \|Df^{-1}\| \|\det Df\|. \quad (7)$$

We introduce the linear change of coordinates  $\Delta_n$  on  $T_{f^n(x)}S$  which is defined in the coordinates  $E_n \oplus F_n$  by the diagonal map  $\Delta_n = \text{Diag}(A_n, B_n)$  where

$$A_n = \sum_{k \geq 0} \lambda^{-k} m_{n+k}/m_n$$

$$B_n = \sum_{k=0}^n \lambda^{k-n} \frac{M_k/M_n}{m_k/m_n}.$$

Assumption (4) and (6) imply that  $A_n$  is finite and  $A_0 \leq C_0$ . Note that  $A_n, B_n$  are larger or equal to 1 so that  $\|\Delta_n\| = A_n B_n$  and  $\|\Delta_n^{-1}\| = A_n^{-1} < 1$ . An easy computation gives:

$$A_{n+1} \frac{m_{n+1}}{m_n} A_n^{-1} = \lambda(1 - A_n^{-1}) < \lambda, \quad (8)$$

$$B_{n+1} \frac{M_{n+1}}{M_n} B_n^{-1} = \lambda^{-1} \frac{m_{n+1}}{m_n} + \frac{M_{n+1}}{M_n} B_n^{-1} > \lambda^{-1} \frac{m_{n+1}}{m_n}. \quad (9)$$

In particular

$$\frac{A_{n+1}}{A_n} \leq \lambda \frac{m_n}{m_{n+1}} \leq \lambda \|Df^{-1}\|, \quad (10)$$

$$A_n \leq A_0 (\lambda \|Df^{-1}\|)^n \leq C_0 (\lambda \|Df^{-1}\|)^n. \quad (11)$$

With (7), we also have

$$\frac{1}{\|Df\| \|Df^{-1}\|} \leq \frac{A_{n+1}}{A_n}. \quad (12)$$

By (4), we have  $m_n/M_n \leq \sigma^n$ . With (5) and (7) one get

$$B_n \leq (\sigma/\lambda)^n \sum_{k=0}^n \left( \lambda \|Df^{-1}\|^2 \|\det Df\| \right)^k \leq (\sigma/\lambda)^n \sum_{k=0}^n (\lambda^2 \|Df^{-1}\|)^{-k} \leq C_0 \left( \frac{\sigma}{\lambda^3 \|Df^{-1}\|} \right)^n. \quad (13)$$

One then defines the local diffeomorphism  $h_n = \Delta_{n+1} \circ g_n \circ \Delta_n^{-1}$  and its tangent part  $H_n := \Delta_{n+1} Dg_n(0) \Delta_n^{-1}$ . The map  $H_n$  has the form  $\begin{pmatrix} a & d \\ 0 & c \end{pmatrix}$ . Using (7), (8), (9), (10) and (12), one gets the estimates

$$\frac{1}{\|Df\| \|Df^{-1}\|^2} \leq |a| = A_{n+1} \frac{m_{n+1}}{m_n} A_n^{-1} < \lambda, \quad (14)$$

$$\begin{aligned} \lambda^{-1}|a| &= \lambda^{-1} A_{n+1} \frac{m_{n+1}}{m_n} A_n^{-1} < |c| = A_{n+1} B_{n+1} \frac{M_{n+1}}{M_n} B_n^{-1} A_n^{-1} \\ &\leq (\|Df\| \|Df^{-1}\| + \lambda \|Df^{-1}\|^2 \|\det Df\|) \end{aligned} \quad (15)$$

$$|d| \leq A_{n+1} \|Df\| A_n^{-1} B_n^{-1} = |a| \frac{m_n}{m_{n+1}} B_n^{-1} \leq \|Df^{-1}\| |a|. \quad (16)$$

In particular, the  $H_n, H_n^{-1}$  are uniformly bounded, and there exists a horizontal cone which is uniformly contracted into itself and whose vectors are uniformly expanded by the  $H_n^{-1}$ .

The  $C^2$ -norm of the diffeomorphisms  $g_n$  is bounded by a constant  $C_f > 0$ , so that

$$\|Dh_n(y) - Dh_n(0)\| \leq \|\Delta_{n+1}\| \|\Delta_n^{-1}\| C_f \|\Delta_n^{-1}\| \|y\| \leq C_f \|\Delta_{n+1}\| \|y\|.$$

Let us choose  $\varepsilon > 0$  small. One can extend  $h_n$  as a global  $C^1$  diffeomorphism  $\hat{h}_n : T_{f^n(x)} S \rightarrow T_{f^{n+1}(x)} S$  which is  $\varepsilon$ -close to the linear map  $H_n$  for the  $C^1$ -topology, and which coincides with  $h_n$  on the ball centered at 0 and of radius

$$r_n := \frac{\varepsilon}{C_f \|\Delta_{n+1}\|} = \frac{\varepsilon}{C_f A_n B_n}. \quad (17)$$

This gives from (11) and (13),

$$r_n > \frac{\varepsilon}{C_f C_0^2} \left( \frac{\lambda^2}{\sigma} \right)^n > \frac{\varepsilon}{C_f C_0^2} \lambda^n.$$

One has obtained a uniformly bounded family of diffeomorphisms  $(\hat{h}_n)$  whose inverses expand uniformly a horizontal cone. The classical stable manifold theorem for sequences of diffeomorphisms (see for instance [KH]) asserts that a uniform family of  $C^1$ -graphs is preserved.

For  $r > 0$  small, the ball of radius  $r$  and centered at 0 in the graph of  $T_x S$  is a curve contracted by the composition  $\hat{h}_{n-1} \circ \dots \circ \hat{h}_0$  by more than  $\lambda^n$ , hence is contained in the ball of radius  $r_n$ . Conjugating by the coordinates changes  $(D_n)$ , this proves that this curve (which has uniform size) is exponentially contracted by the  $g_n$ , hence is a stable manifold. All the constants are still valid for  $C^2$ -diffeomorphisms that are  $C^1$ -close to  $f$  and have the same  $C^2$ -norm  $C_f$ . Since the stable manifold for sequences of diffeomorphisms depends continuously on  $(\hat{h}_n)$  for the  $C^1$ -topology, the stable manifold for the surface diffeomorphism depends continuously on  $(x, f)$ .  $\square$

### 3 Robustness: proof of theorem 1

The proof will require preliminary results that we give now. We first state a version of Pliss lemma (whose proof is similar to [M, Lemma 11.8]).

**Lemma 3.1.** *For any  $\alpha_1 < \alpha_2 < \alpha_3$ , and any sequence  $(a_n) \in (\alpha_1, +\infty)^{\mathbb{N}}$  satisfying*

$$\limsup_{+\infty} \frac{1}{n} (a_0 + \dots + a_{n-1}) \leq \alpha_2,$$

*there exists a collection of integers  $0 \leq n_1 < n_2 < \dots$  such that*

- for any  $k \geq 1$  and  $n > n_k$ , one has  $\frac{1}{n-n_k} (a_{n_k} + \dots + a_{n-1}) \leq \alpha_3$ ,*
- the upper density  $\limsup \frac{n_k}{k}$  of the sequence  $(n_k)$  is larger than  $\frac{\alpha_3 - \alpha_2}{\alpha_3 - \alpha_1}$ .*

For any  $C^1$ -diffeomorphism  $g$  and  $\sigma \in (0, 1)$ , we introduce the compact set  $A_\sigma(g)$  of points  $x \in S$  such that there exists a one-dimensional subspace  $E \subset T_x S$  satisfying (4) for each  $n \geq 0$ . Note that under our assumptions on  $g$ , one has:

$$\|Dg^{-1}\|^{-1} \geq \min_x \frac{|\det Dg(x)|}{\|Dg(x)\|} > b^{16/15} K^{-1}.$$

The previous lemma has the following consequence.

**Lemma 3.2.** *For any  $K > 1$  and  $b \in (0, K^{-60})$ , consider a  $C^1$ -diffeomorphism  $g$  satisfying*

$$\|Df(x)\| < K \text{ and } b^{16/15} < |\det f(x)| \leq b \text{ at any point } x \in S$$

*and an ergodic measure  $\nu$  having a non-negative Lyapunov exponent. Then  $\nu(A_\sigma(g)) > 1/3$  with  $\sigma = b^{4/5}$ .*

*Proof.* Let  $\chi^- < 0 \leq \chi^+$  be the two Lyapunov exponents of  $\nu$ . We have  $\chi^+ \in (0, \log(K))$  and  $\chi^- \leq \log |\det(Df(x))| \leq \log(b)$ . Let us apply Lemma 3.1 to the sequence  $\log \|Dg(g^n(x))\|_{E^s}$ , where  $x$  satisfies the Oseledets theorem for the measure  $\nu$ . One chooses  $\alpha_1$  smaller than the infimum  $\|Dg^{-1}\|^{-1}$  of  $\log\{\|Dg.v\|/\|v\|\}$ , one takes  $\alpha_2$  equal to the smallest Lyapunov exponent  $\chi^-(\nu)$  of  $\nu$  and  $\alpha_3 = \log(\sigma) = \frac{4}{5} \log(b)$ . Then, the set of iterates  $g^{n_i}(x)$  satisfying  $\|Dg^n(g^{n_i}(x))\|_{E^s} \leq \sigma^n$  for each  $n \geq 0$  has density larger than

$$\frac{\alpha_3 - \alpha_2}{\alpha_3 - \alpha_1} > \frac{(4/5 - 1) \log(b)}{(4/5 - 16/15) \log(b) + \log(K)} > \frac{2}{3},$$

provided  $b$  is smaller than  $K^{-30}$ .

Let us now apply Lemma 3.1 to the sequence  $\log \frac{\|Dg(g^n(x))\|_{E^s}^2}{|\det Dg(g^n(x))|}$ . As before, it is bounded from below by  $\alpha'_1 = \log(b^{16/15}/K^2)$ , and its Cesaro averages converge to  $\alpha'_2 = \chi^- - \chi^+$  which is bounded from above by  $\log(b)$ . One takes  $\alpha'_3 = \frac{4}{5} \log(b)$ . Then, the set of iterates  $g^{n_i}(x)$ , satisfying  $\|Dg^n(g^{n_i}(x))\|_{E^s}^2 \leq \sigma^n |\det Dg(g^{n_i}(x))|$  for each  $n \geq 0$ , has density larger than

$$\frac{\alpha'_3 - \alpha'_2}{\alpha'_3 - \alpha'_1} > \frac{(4/5 - 1) \log(b)}{(4/5 - 16/15) \log(b) + \log(K)} > \frac{2}{3},$$

provided  $b$  is smaller than  $K^{-60}$ .

The measure  $\nu(A_\sigma(g))$  is bounded from below by the density of iterates  $g^{n_i}(x)$  satisfying these two conditions, hence is bounded from below by  $2 \times \frac{2}{3} - 1 = \frac{1}{3}$ .  $\square$

Let  $f$  be a diffeomorphism as in the statement of theorem 1 and let  $\sigma = b^{4/5}$ . Then the condition (3) follows from (1) provided  $b < K^{-15}$ . For any diffeomorphism  $g \in \text{Diff}_C^{1+\alpha}(S)$  that is  $C^1$ -close to  $f$ , one introduces the set:

$$X(g) := \{x \in U \cap A_\sigma(g), \text{ the branches of } W^s(x) \text{ are not contained in } f(\bar{S})\}.$$

The continuity of the stable manifold obtained in Theorem 5 gives:

**Lemma 3.3.** *Let  $x \in X(f)$ . If  $g$  is  $C^2$ -close to  $f$ , and if  $y \in A_\sigma(g)$  is close enough to  $x$ , then  $y$  belongs to  $X(g)$ .*

One can now give the proof of the theorem.

*Proof of theorem 1.* One chooses  $\sigma$  as before. It is enough to check that for any diffeomorphism  $g \in \text{Diff}_C^{1+\alpha}(S)$  that is  $C^1$ -close to  $f$ , and for any ergodic measure  $\nu$  of  $g$  which is not a hyperbolic sink,  $\nu(X(g))$  is non-zero.

One can argue by contradiction, consider a sequence of diffeomorphisms  $(g_n)$  in  $\text{Diff}_C^{1+\alpha}(S)$  which converge to  $f$  in the  $C^1$ -topology, and a sequence of ergodic measures  $\nu_n$  (not supported on hyperbolic sinks) converging to an invariant measure  $\mu$  of  $f$  and assume that  $\nu_n(X(g_n)) = 0$  for each  $n$ . Note that if  $\mu$  gives positive measure to a hyperbolic sink, then  $\nu_n$ ,  $n$  large, gives positive measure to the hyperbolic continuation of the sink, which is a contradiction. We may now assume that  $\mu$ -almost every point has one negative Lyapunov exponent and one non-negative Lyapunov exponent. The same holds for  $\nu_n$ . Up to consider a subsequence, one can assume that  $(A_\sigma(g_n))$  converges for the Hausdorff topology. Note that the limit is contained in  $A_\sigma(f)$ .

From Lemma 3.2, there exists a family of compact sets  $Z_n \subset A_\sigma(g_n)$  with  $\nu_n$ -measure larger than  $1/3$  which converge to a compact set  $Z \subset A_\sigma(f)$ , whose  $\mu$ -measure is larger or equal to  $1/3$ . Since the support of  $\mu$  is disjoint from the hyperbolic sinks of  $f$ , the set  $Z \cap X(f)$  has also measure larger or equal to  $1/3$ . Hence, up to take slightly smaller subsets, one can assume furthermore that  $Z \subset X(f)$ . Lemma 3.3 (and a compactness argument) implies that for  $n$  large enough,  $Z_n$  is contained in  $X(g_n)$ . This proves that  $\nu_n(X(g_n)) > 0$  which is a contradiction. This ends the proof of theorem 1.  $\square$

## 4 Strong dissipation for dynamics close to one-dimensional endomorphisms: proof of theorem 2

We explain in this section how to build naturally dissipative surface diffeomorphisms from one-dimensional systems acting on an interval or the circle.

**Definition of the two-dimensional extension.** Given a one-dimensional manifold  $I$  (the circle  $S^1$  or the interval  $(0, 1)$ ), a  $C^r$  map  $h: I \rightarrow I$  isotopic to the identity (such that  $h(\partial I) \subset \text{Interior}(I)$  in the case of the interval) and  $b \in (-1, 1)$ ,  $\varepsilon > 0$  small enough, we get a map  $f_b$  on  $S := I \times (-\varepsilon, \varepsilon)$  defined by

$$f_b: (x, y) \mapsto (h(x) + y, b(h(x) - x + y)). \quad (18)$$

Indeed for any  $y \in \mathbb{R}$  close to 0 and any  $x \in h(I)$ , the sum  $x + y$  is well defined and, since  $h$  is isotopic to the identity, the difference  $h(x) - x$  belongs to  $\mathbb{R}$ .

Note that the Jacobian is constant and equal to  $b$ . When  $b \neq 0$ , the map  $f_b$  is a diffeomorphism onto its image. When  $b = 0$  the image  $f_0(S)$  is contained in  $I \times \{0\}$  and the restriction of  $f_0$  coincides with  $f \times \{0\}$ .

**Example 4.1.** Let us consider the *quadratic family*  $x \mapsto x^2 + c$ , for  $c \in (-2, -1)$ . It sends the interval  $I = (c/2 - 1, -c/2 + 1)$  into its interior. The map  $f_b$  in this case is conjugate to the *Hénon map* (2) with parameter  $a = -b^2/4 - c - b/2$  through the map  $(x, y) \mapsto (-ax - b/2, -ay - abx)$ .

**Example 4.2.** A class of circle maps isotopic to the identity is the *Arnol'd family* on  $S^1$ :

$$h_{a,\omega}: x \mapsto x + a \sin(2\pi x) + \omega, \quad a, \omega \in \mathbb{R}. \quad (19)$$

We can now state the general version of Theorem 2.

**Theorem 2** (General version). *If  $h: I \rightarrow I$  is a one-dimensional  $C^2$ -map isotopic to the identity such that  $h(\partial I) \subset \text{interior}(I)$  and if  $b \in \mathbb{R}$  is close enough to 0, then any map  $C^2$ -close to  $f_b$  is strongly dissipative.*

*Proof.* Let  $K > 1$  such that  $\|Dh\| < K$  and  $\|Df_b\| < K$  for any  $b$  close to 0. Note that

$$\frac{|b|}{5K} \leq \|Df_b^{-1}\|^{-1} < |b|.$$

We choose a uniform  $L \gg K$  and for any  $b$  close to 0 we set  $\sigma(b) := L|b|$  and  $\lambda(b) := L^2|b|$ . Since  $\det(Df_b) = b$ , the conditions (3) and 5 are satisfied once  $|b|$  is small enough.

For each  $f = f_b$ , we introduce the set  $\mathcal{A}_\sigma = \mathcal{A}_\sigma(f_b)$  of points  $x$  having a direction  $E \subset T_x S$  satisfying (4). If  $|b|$  is small enough, the proof of Lemma 3.2 shows that, for any ergodic measure  $\nu$  having a non-negative Lyapunov exponent,  $\nu(\mathcal{A}_\sigma) > 1/3$ . In particular  $\mathcal{A}_\sigma$  is non-empty.

Our goal now is to prove that both branches of the stable manifold of points of  $\mathcal{A}_\sigma$  intersect  $S \setminus f_b(S)$ . For that purpose we recast the proof of theorem 5 in order to get a uniformity for the local stable manifold of points in  $\Lambda_k$ .

**Lemma 4.3.** *For any  $\eta > 0$ , there are  $r_0, b_0 > 0$  such that any map  $f_b$ ,  $|b| < b_0$  has the following property: at any  $x_0 \in \mathcal{A}_\sigma$ , the  $r_0$ -neighborhood of  $x_0$  in  $W^s(x_0)$  is a disc of length  $2r_0$  which is  $\eta$ -close to a linear segment: all the tangent spaces are  $\eta$ -close to a fixed direction.*

*Proof.* One reproduces the constructions made at section 2, keeping the dependence in  $|b|$ . Note in particular that the quantity  $C_0$  in (6) is uniform in  $b$ .

As before, one defines a local diffeomorphism  $h_n = \Delta_{n+1} \circ g_n \circ \Delta_n^{-1}$  from a neighborhood of  $0 \in T_{f^n(x)} S$  to a neighborhood of  $0 \in T_{f^{n+1}(x)} S$ . Its tangent map  $H_n$  has an inverse of the form

$$H_n^{-1} = \begin{pmatrix} \frac{1}{a} & \frac{-d}{ac} \\ 0 & \frac{1}{c} \end{pmatrix} = \frac{1}{a} \begin{pmatrix} 1 & \frac{-d}{c} \\ 0 & \frac{c}{c} \end{pmatrix}.$$

From (15) and (16), we have

$$\left| \frac{a}{c} \right| \leq \lambda \leq L\sigma, \quad \text{and} \quad \left| \frac{d}{c} \right| \leq \|Df^{-1}\| \lambda \leq 15K.L.$$

One deduces that there exists an horizontal cone which is contracted by any linear map which is  $\frac{1}{2a}$ -close to  $H_n^{-1}$ . The horizontal cone can be chosen arbitrarily thin if  $|b|$  is small enough. Let  $\eta > 0$  be the size of the horizontal cone (i.e.  $\min(\|u - v\|, \|u + v\|) < \eta$  for any unit vectors  $u, v$  in the cone).

The  $C^2$ -norm of  $g_n^{-1}$  is bounded by  $C.b^{-2}$ , where  $C$  is uniform in  $b$ . This shows that  $Dh_n^{-1}$  is  $\frac{\eta}{2a}$ -close to  $H_n^{-1}$  on a ball of radius

$$r_{n+1} = \frac{\eta|b|^2}{2C.a.\|\Delta_n\|.\|\Delta_{n+1}^{-1}\|^2}.$$

Since  $\|\Delta_{n+1}^{-1}\| < 1$  and  $\|\Delta_n\| = A_n B_n$ , the estimates (14), (11), (13) imply

$$r_{n+1} \geq \frac{\eta|b|^2}{2CC_0^2\lambda} \cdot \left(\frac{\lambda^2}{\sigma}\right)^n = \frac{\eta}{2CC_0^2L^5} \cdot \left(L^3.b\right)^{n+1}.$$

The maps  $Dh_n^{-1}$  expand vectors in the horizontal cone by more than  $\lambda^{-1} = (L.b)^{-1}$  from (14). One deduces that there exists a Lipschitz graph containing 0 in  $T_x S$  with uniform size whose iterates by the sequence of local diffeomorphisms  $h_n$  remain Lipschitz for each  $n$ , and after  $n$  iterates has length smaller than  $r_n$ .

Projecting in  $S$ , by  $\exp \circ \Delta_0$ , one gets a local stable manifold at  $x$  with uniform size  $2r_0$  and tangent to the projection of the constant horizontal cone which is  $\eta$ -thin.  $\square$

It remains to control the slope of the local stable manifolds. This is done outside a neighborhood of a “critical region”. Let us fix  $\delta > 0$  such that  $\frac{\log K}{\log K + |\log \delta|} < 1/6$  and define

$$\mathcal{C} = \{x, |Dh(x)| \leq \delta\} \times (-\varepsilon, \varepsilon).$$

**Lemma 4.4.** *For  $|b_k|$  small enough,  $\nu_k(\mathcal{A}_\sigma \setminus \mathcal{C}) > 1/6$ .*

*Proof.* It is enough to check that  $\nu_k(\mathcal{C}) < 1/6$ , hence that  $\mu(\mathcal{C}) < 1/6$ . Note that the Lyapunov exponent of  $\mu$  is bounded above by  $\mu(\mathcal{C}) \log(\delta) + (1 - \mu(\mathcal{C})) \log \|Dh\|$ . Since  $\mu$  does not charge sinks, the exponent is non-negative so that

$$\mu(\mathcal{C}) \leq \frac{\log K}{\log K + |\log \delta|} < 1/6.$$

$\square$

**Lemma 4.5.** *For points  $z$  in  $\mathcal{A}_\sigma \setminus \mathcal{C}$ , the slope of the direction  $E$  is larger than  $\frac{3}{4}\delta$ .*

*Proof.* Let  $z = (x, y)$ , let  $v$  be a unit vector tangent to  $E$  and let  $\alpha$  be the angle between  $v$  and the line  $\mathbb{R} \times \{0\}$ . From (4), its image has norm smaller or equal to  $\sigma$ . From the definition of  $f_b$ , the first projection of  $Df_b.v$  has a modulus larger than  $\|Dh(x)\| |\cos(\alpha)| - |\sin(\alpha)|$ . Since  $z$  does not intersect  $\mathcal{C}$ , the modulus  $\|Dh(x)\|$  is larger than  $\delta$ . One thus gets  $|\tan(\alpha)| \geq \delta - \sigma/|\cos(\alpha)|$  which implies that the slope is larger than  $3\delta/4$  when  $\sigma = |b|^{4/5}$  is small enough.  $\square$

*End of the proof of theorem 2* For points in  $\mathcal{A}_\sigma \setminus \mathcal{C}$ , the stable manifold has uniform size and slope larger than  $\delta/2$ . Consequently, if  $\varepsilon$  has been chosen small enough, this proves that for  $b_k$  small and for points in  $\mathcal{A}_\sigma \setminus \mathcal{C}$ , both branches of the stable manifold intersect the boundary of  $I \times (-\varepsilon, \varepsilon)$ . This contradicts our assumption on the measures  $\nu_k$ .  $\square$

## 5 Reduction to one-dimensional dynamics: proof of theorem 3

One chooses a countable collection  $\Gamma$  of proper  $C^1$ -arcs in  $\mathbb{D}$  with the following properties.

1. Each  $\gamma \in \Gamma$  is contained in the stable manifold  $W^s(x)$  of a regular point  $x$  for an aperiodic ergodic measure (but  $x$  is not necessarily in  $\gamma$ ). In particular, elements of  $\Gamma$  are pairwise disjoint or coincide.
2. Each  $\gamma \in \Gamma$  is the  $C^1$ -limit of arcs in  $\Gamma$  and is accumulated on both sides.
3. For  $\gamma \in \Gamma$ , the connected components of  $f^{-1}(\gamma) \cap \mathbb{D}$  which intersect  $f(\mathbb{D})$  are also in  $\Gamma$ .
4. For each aperiodic ergodic measure  $\mu$ , there exists a full measure set of points  $x$  such that the connected components of  $W^s(x) \cap \mathbb{D}$  are  $C^1$ -limits of arcs in  $\Gamma$  and are accumulated on both sides.

**The space  $X$ .** One considers open connected surfaces  $s$  of  $\mathbb{D}$  bounded by finitely many elements of  $\Gamma$ . One denotes  $\Sigma$  the collection of sequences  $(s_n)$  of such surfaces such that  $\text{Closure}(s_{n+1}) \subset s_n$  for each  $n$  and one sets  $(s_n) \leq (s'_n)$  if for any  $n$ , there is  $m$  such that  $\text{Closure}(s_m) \subset s'_n$ . Let  $\Sigma_0$  be the collection of sequences that are minimal for the relation  $\leq$ . One defines  $X$  as the quotient of  $\Sigma_0$  by the relation “ $(s_n) \leq (s'_n)$  and  $(s'_n) \leq (s_n)$ ”. Note that  $\Gamma$  may be identified to a subset of  $X$ : the arc  $\gamma$  is represented by sequences  $(s_n)$  such that  $\gamma \subset s_n$  for each  $n$  and  $\cap s_n = \gamma$ ; such a sequence exists from our assumption 2 on  $\Gamma$ .

One defines a topology on  $X$ . A (countable) basis is defined by considering all the sequences  $(s_n)$  such that the closure of  $s_n$  is contained in a given surface  $s$  for  $n$  large enough. Note that  $X$  is separated. Moreover it is regular: any non-empty closed set  $C$  and any point  $x$  in the complement can be separated. Indeed, since  $C$  is closed,  $x$  has a neighborhood, defined by a surface  $s$ , disjoint from  $C$ . By definition of  $\Gamma$ , one can build two surfaces  $s \supset s_1 \supset s_2 \supset x$ . The surface  $s_2$  defines a neighborhood of  $x$ . The complement of the closure of  $s_1$  defines a neighborhood of  $C$ . Both are disjoint.

**Lemma 5.1.**  *$X$  is a real tree.*

*Proof.* The space  $X$  is metrizable, by Urysohn theorem (a separated, countable basis, regular topological space is metrizable).

The space  $X$  is compact. Indeed, let  $(x_k)$  be a sequence in  $X$  and consider the collection  $(\gamma_n)$  of arcs of  $\Gamma$ . One can assume, for each  $n$  that the sequence  $(x_k)$  is different from  $\gamma_n$  for each  $k$  large, hence (up to take a subsequence) is contained in a same component of the complement of  $\gamma_n$ . One defines in this way a minimal decreasing sequence  $s_n$  of surfaces and all the  $x_k$ ,  $k$  large, belong to  $s_n$ . Thus the sequence  $(x_k)$  converges to the point defined by  $(s_n)$ .

One say that  $x$  separates  $y$  and  $z$  if for any small neighborhood of  $x$  (defined by a surface  $s$ ),  $y$  and  $z$  are contained in different components of the complement of  $s$ . Let us index the elements of  $\Gamma$  and consider the subfamily  $(\gamma_n)$  of those that separate  $y$  and  $z$ . They are ordered by the separation property. The maximum of the distance between two consecutive  $\gamma_n$ ,  $n \leq n_0$ , goes to zero as  $n_0$  goes to  $\infty$ . Otherwise, one gets two sequences  $\gamma_{n_k}$ ,  $\gamma_{m_k}$ , the first increasing, the second decreasing, for the order between points that separate  $y$  and  $z$ . Moreover the distance  $d(\gamma_{n_k}, \gamma_{m_k})$  does not converge to 0. These sequences converge to two different points  $a, b$  that separate  $y$  to  $z$ . Since  $a, b$  are different, there should exist  $\gamma_n$ ,  $n$  large, that separate  $a$  to  $b$ , contradicting the construction of  $a$  and  $b$ . This proves that the union of  $\{y, z\}$  with the set of points which separate  $y$  and  $z$  is homeomorphic to the interval  $[0, 1]$ . Thus  $X$  is path connected. Note that any path joining  $y$  to  $z$  should contain this set of point (since they separate). This shows that  $X$  is a real tree.  $\square$

**The maps  $\pi, h$ .** Any point  $\gamma \in \Gamma$  naturally projects to  $X$ . For each point  $x \in \mathbb{D} \setminus \bigcup \{\gamma \in \Gamma\}$ , one can consider the component  $s_n$  of  $\mathbb{D} \setminus \{\gamma_1 \cup \dots \cup \gamma_n\}$  which contains  $x$ . One gets in this way a minimal decreasing sequence which defines a point  $\pi(x) \in X$ . This map  $\mathbb{D} \rightarrow X$  is obviously continuous.

The map  $f$  induces a continuous map  $h$  on  $X$ , defined as follow. Let  $(s_n)$  be a minimal decreasing sequence and consider the intersection  $C$ . Any two points  $y, z$  in  $C$  have their image by  $f$  which are not separated by a curve  $\gamma$ . Otherwise, this curve  $\gamma$  crosses  $f(\mathbb{D})$ , the pre image  $f^{-1}(\gamma)$  has a connected component separating  $y, z$ , which belongs to  $\Gamma$  from the assumption 3; this proves that the family  $\Gamma$  separates  $y$  and  $z$ , a contradiction. The image of the point  $x = \pi(C)$  by  $h$  is  $\pi(f(C))$ .

Note that points that are regular for different aperiodic ergodic measures belong to different stable arcs, hence are mapped to different points in  $X$  by the assumption 4. Thus different aperiodic ergodic measures project to different measures on  $X$ .

The proof of theorem 3 is now complete.  $\square$

## 6 Density of periodic points: proof of theorem 4

**One dimensional sketch.** First we prove of theorem 4 in the context of one-dimensional dynamics (our statement is slightly more general than [Y, theorem 1]).

**Proposition 6.1.** *For any continuous map  $f: [0, 1] \rightarrow [0, 1]$ , the set of periodic points is dense in the set of recurrent points.*

*Proof.* Let us consider a recurrent point  $x_0$  and a nearby iterate  $x_1 = f^n(x_0)$ . Without loss of generality, one can assume that  $x_0 < x_1$ . We claim that there is a periodic point for  $g := f^n$  inside  $(x_0, x_1)$ . Note that  $x_0$  is still recurrent for  $g$ .

We define the intervals  $D^- = [0, x_0]$  and  $D^+ = [x_1, 1]$  and we take the first positive integer  $k$  such that  $g^k(x_1) \notin D^+$ . Such an integer exists since  $x_0$  is recurrent and does not belong to  $D^+$ . Let  $h: [0, 1] \rightarrow [x_0, x_1]$  be a continuous map which coincides with the identity on  $[x_0, x_1]$  and such that  $h([0, x_0]) = x_0$ ,  $h([x_1, 1]) = x_1$ . Then the map  $h \circ g^k: [a, b] \rightarrow [x_0, x_1]$  has a fixed point  $p \in [x_0, x_1]$ . Note that  $h \circ g^k(x_0) = x_1$  (since  $g^k(x_0) \in D^+$ ) and  $h \circ g^k(x_1) \neq x_1$  (since  $g^k(x_1) \notin D^+$ ). Therefore  $p$  belongs to  $(x_0, x_1)$ . Since  $h$  is the identity on  $(x_0, x_1)$ , the point  $p$  is a fixed point of  $g^k$ .  $\square$

The key factor in previous argument is a simple one: *a point disconnect an interval*. The last observation does not have an immediate two-dimensional counterpart (points does not separate a two dimensional domain). However, local stable manifolds, under the assumption of strong dissipativeness, does separate a two dimensional domain.

**Proof of theorem 4.** Let us recall first some classical result and definitions about invariant measure and Pesin theory.

**Lemma 6.2.** *Let  $f$  be  $C^r$ -diffeomorphism,  $r > 1$  of a surface  $S$ . Let  $\mu$  be an ergodic invariant measure with compact support having two Lyapunov exponents  $\lambda^- < 0 \leq \lambda^+$ .*

*Then there exist  $C, \lambda > 0$ , a compact set  $B$  with positive  $\mu$ -measure (called Pesin block) and a continuous family of  $C^1$ -embeddings  $(\varphi_x)_{x \in B}$  of  $[-1, 1]$  into  $S$  such that for  $x \in B$ ,*

- $\varphi_x(0) = x$  and the stable manifold  $W^s(x)$  contains the image of  $\varphi_x$ ,
- for any  $n \geq 0$ , the length of  $f^n(\varphi_x([-1, 1]))$  is smaller than  $Ce^{-\lambda \cdot n}$ .

*Proof.* From [Pe], there exists a measurable set  $X \subset S$  with positive measure and a measurable family of  $C^1$ -embeddings  $(\varphi_x)_{x \in X}$  such that the image of  $\varphi_x$  is a local manifold of  $x$ . Lusin's theorem allows to find a compact set  $B \subset X$  as required.  $\square$

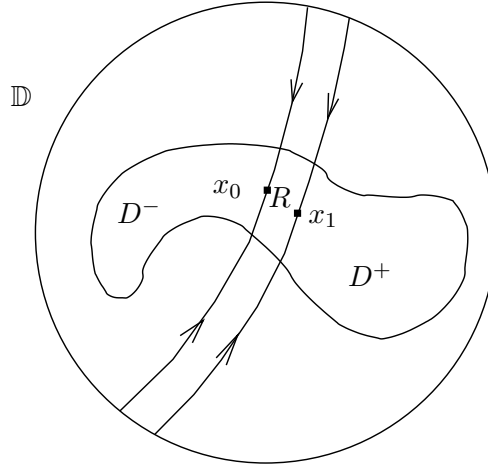

To prove the theorem, since any regular point has an iterate in a hyperbolic block, it is enough to show that arbitrary close to any point  $x \in B$  there is a periodic point. By Poincaré recurrence theorem, one can assume that any point in  $B$  is positively recurrent.

Since  $f$  is strongly dissipative, both branches of  $W^s(x_0) \setminus \{x_0\}$  meets  $S \setminus f(S)$ . For any  $\delta > 0$ , it is thus possible to find a forward iterate  $f^n(S)$  which intersect both branches at two points  $\delta/2$ -close to  $x$  in  $W^s(x)$ . Moreover one can modify the boundary of  $f^n(S)$  in order to get a  $C^1$ -loop  $\gamma$  transverse to  $W^s(x)$ . The disc  $D \subset S$  bounded by  $\gamma$  still satisfy  $f(\overline{D}) \subset \text{Interior}(D)$ .

Let  $n \geq 1$  be a large integer such that  $f^n(x)$  belongs to  $B$  and is close to  $x$ . Then by Lemma 6.2, the local manifold of  $f^n(x)$  is  $C^1$ -close to the local manifold of  $x$ , and in particular is also transverse to  $\gamma$ . One deduces that the connected components of  $W^s(x) \cap D$  and  $W^s(f^n(x)) \cap D$  containing respectively  $x, f^n(x)$ , together with small arcs in  $\gamma$  enclose a region  $R$  diffeomorphic to the square. If  $m$  has been chosen large enough, the diameter of  $R$  is smaller than  $1\delta$ . Moreover  $D \setminus R$  has two connected components, whose closure are two topological discs, denoted by  $D^+, D^-$ : for instance one can choose  $x \in D^-$  and  $f^n(x) \in D^+$ . By construction  $D^- \cap R$  (resp.  $D^+ \cap R$ ) is contained in the local stable manifold of  $x_0 := x$  (resp.  $x_1 := f^n(x)$ ). See the figure.

Let  $g = f^k$  and let  $k$  be the smallest positive integer such that  $g^k(x_0) \in D^+$  and  $g^{k+1}(x_0) \notin D^+$ . Such an integer exists since  $x_0$  is recurrent for  $g$  and since  $x_1 = g(x_0) \in D^+$ . Similarly as in the one dimensional case, we consider a continuous map  $h: D \rightarrow R$  such that the restriction of  $h$  to  $R$  is the identity,  $h(D^-) = D^- \cap R$ ,  $h(D^+) = D^+ \cap R$ . In particular,  $h \circ g^k$  sends  $R$  into itself and therefore has a fixed point  $p$  in  $R$ .

Since  $f^k(x_0) \in D^+$  and since  $D^- \cap R$  is the local stable manifold of  $x_0$ , its image meets  $D^+$  (and is contained in  $D$ ); since  $D^+ \cap R$  is also a stable manifold, either it contains or it is disjoint from  $f^k(D^- \cap R)$ . Consequently  $f^k(D^- \cap R) \subset D^+$ . Similarly,  $f^k(x_1) \notin D^+$ , hence  $f^k(D^- \cap R) \cap D^+ = \emptyset$ .

One deduces that  $p$  does not belong to  $R \cap (D^+ \cup D^-)$ : by definition of  $h$  it has a unique pre image and  $h^{-1}(p) = p$ . This implies  $g^k(p) = p$ . Hence  $f$  has a periodic point arbitrarily close to  $x$ , as required.  $\square$

**Proof of corollary 1.2.** Let us fix  $a \in (1, 2)$  and define  $S = \{(x, y) : |x| < 1/2 + 1/a, |y| < 1/2 - a/4\}$  and  $C := \{(x, y), |x| > |y| \text{ and } |x| > 3\}$ . Note that the following properties hold:

- $f(C) \subset C$  and any forward orbit  $(x_n, y_n) := H_{a,b}^n(x, y)$  in  $C$  satisfies  $|x_n| \xrightarrow{n \rightarrow +\infty} \infty$ .
- Any point  $(x, y)$  has a positive iterate in  $S$  or in  $C$ .
- The quadratic map  $x \mapsto 1 - ax^2$  has a unique fixed point in  $(-3, -1/2 - 1/a)$  and any other orbit escape this interval. Consequently, if one fixes  $\varepsilon > 0$  small enough, for any  $b$  close to 0, the map  $H_{a,b}$  has a unique fixed point  $p$  in  $(-3, -1/2 - 1/a) \times (-\varepsilon, \varepsilon)$ . Moreover if  $b$  is close enough to 0, any point in  $(-3, -1/2 - 1/a) \times (-\varepsilon, \varepsilon)$  has a forward iterate in  $S$  or in  $C$ .
- If  $b$  is chosen close to 0, the region  $\{|x| < 3, |y| < 3\}$  is mapped by  $H_{a,b}$  in the union of  $C$  with  $(-3, -1/2 - 1/a) \times (-\varepsilon, \varepsilon)$ .

One deduces:

**Lemma 6.3.** *For any  $a \in (1, 2)$ , if  $|b| > 0$  is close enough to 0, the Hénon map has a unique fixed point  $p$  in  $(-3, -1/2 - 1/a) \times (-1, 1)$  and any forward orbit satisfies one of the following properties:*

- it escape to infinity (the orbit has no accumulation point in the plane),
- it converges to  $p$ ,
- it is attracted by the trapping region  $S = \{(x, y) : |x| < 1/2 + 1/a, |y| < 1/2 - a/4\}$ .

Since the dynamics of  $H_{a,b}$  is strongly dissipative in  $S$  (theorem 2), the theorem 4 may be applied in this region and concludes the proof.  $\square$
